## Datasheet SHF 78210 C Synthesized Clock Generator

**SHF 78210 C** Synthesized Clock Generator Power 

Input		Output	
10 MHz Ref 3.3 Vpp Max	Modulation 1.2 Vpp Max	Trigger < 0.7 Vpp	RF < 8 dBm 
			
50 Ω / SMA Female		50 Ω / SMA Female	50 Ω / 1.85 mm Male

## Description

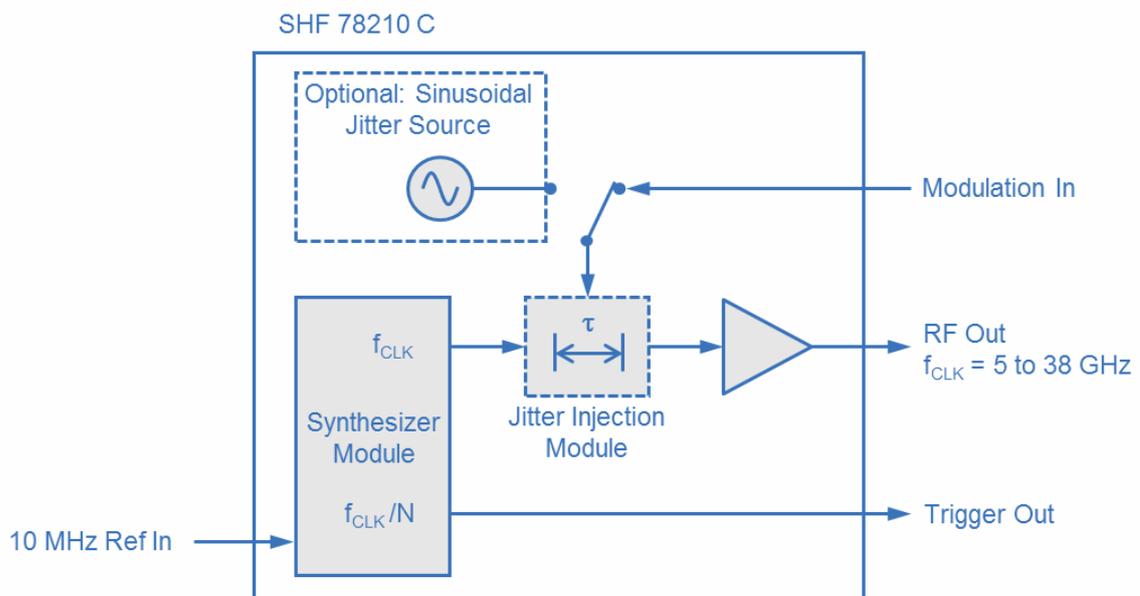

The Synthesized Clock Generator SHF 78210 C is designed to provide our BERT system customers with a suitable internal clock source at reasonable cost. It is a field replaceable plug-in module which needs to be installed in an SHF mainframe. Together with other plug-in modules from this instruments series, a modular and scalable measurement system can be put together.

It features a wide frequency range **from 5 GHz to 38 GHz**, a large output power range variable from **-10 dBm to +8 dBm** in 0.1 dB steps and it generates low jitter clock signals. For frequencies above 10 GHz, additional band-pass filtering ensures low harmonic levels. From 5 to 10 GHz, short rise time clock signals are generated in a trade-off for increased levels of higher-order harmonics.

The **jitter injection** functionality is integrated for jitter stress test applications. Arbitrary jitter types may be applied to the clock signal using an external signal source, enabling various test scenarios such as data protocol compliance testing. An optional internal jitter source provides sinusoidal jitter from 10 to 400 MHz with variable jitter amplitude.

An additional **trigger output** provides a trigger signal whose frequency can be switched to a quarter or half the output frequency. The trigger remains jitter-free even if jitter injection is used.

## Block Diagram

## Features

- Output clock frequency ranges from  $f_{CLK} = 5$  to 38 GHz with 1 MHz resolution
- Output power adjustable from -10 to +8 dBm with 0.1 dB resolution
- External jitter modulation
- Supports three spread-spectrum clocking (SSC) modes
- 10 MHz reference input for phase locking to other instruments
- Remote programming interface for automated measurements

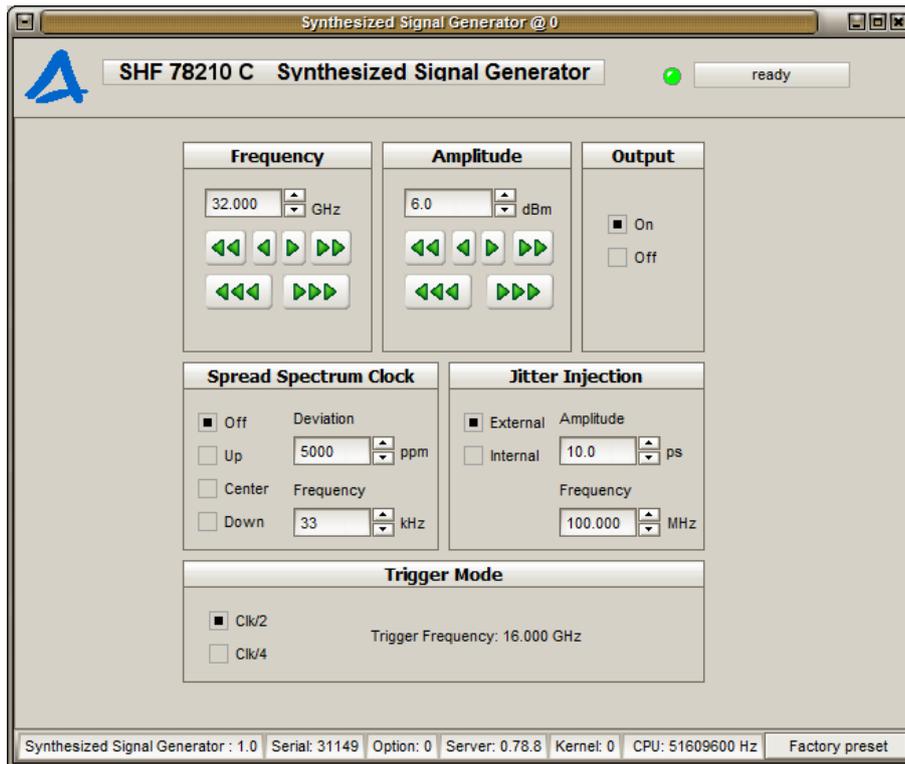

## Ease of Use

The SHF 78210 C is operated inside an SHF mainframe and controlled by an external computer (not part of the delivery). Every system comes along with the intuitive, easy to use BERT Control Center software (BCC). The BCC provides the user friendly interface for changing the device parameters.

Additionally, the instrument may be programmed remotely over the Ethernet connection for automated tests and measurements. Please refer to the *SHF BERT Programming Manual*.

Note that SHF also offers the compact standalone Synthesized Clock Generator SHF 78120 A. Please visit [www.shf.de](http://www.shf.de) for further details.

Graphical User Interface

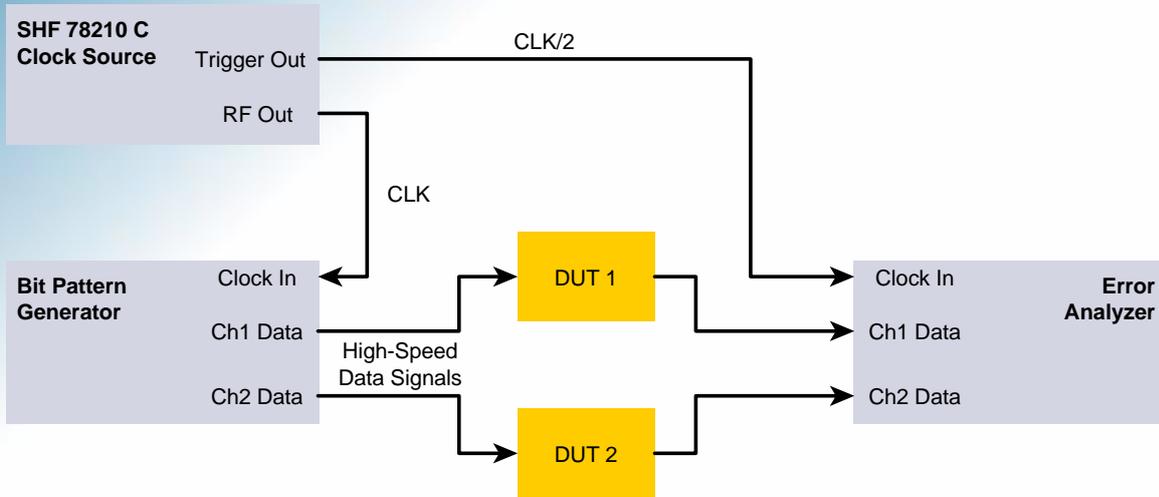

## Options

### Option ISJ: Internal Sinusoidal Jitter Source

Several data communication standards require jitter tolerance and jitter transfer testing for sinusoidal jitter over a specified jitter frequency range. The optional internal sinusoidal jitter source allows stress tests for jitter frequencies ranging from 10 to 400 MHz. Jitter amplitudes up to 60 ps may be generated. The jitter amplitude is calibrated depending on the jitter frequency and on the clock frequency.

# Applications

Typical Multi-Channel Test Setup

## Specifications

Parameter	Symbol	Unit	Min.	Typ.	Max.	Comment
<b>Clock Output (RF Out)</b>						
Operating Frequency	$f_{CLK}$	GHz	5		38	
Frequency Resolution		MHz		1		
Frequency Accuracy					$10^{-5}$	Using internal reference
Frequency Stability			$10^{-6}$		$10^{-5}$	Ambient temperature 21°C
Frequency Stability Aging		ppm			3	per year
Output Power Level	$P_{out}$	dBm	-10		+8	
Output Power Resolution		dB			0.1	
Output Power Accuracy		dB			1	
Harmonics/Spurious Signals		dBc			-20	For $f_{CLK} \geq 10$ GHz
Phase Noise		dBc/Hz		tbd		
Jitter (RMS)	$J_{RMS}$	fs			400	On scope display (not deconvolved) <sup>1</sup>
Output Impedance		$\Omega$		50		
Connector						1.85 mm (V) male

<sup>1</sup> Measured with Agilent 86100A, 70 GHz sampling head and precision time base triggered by clock signal from RF Out.

Parameter	Symbol	Unit	Min.	Typ.	Max.	Comment
<b>Trigger Out</b>						
Frequency		GHz	1.25		19	
Output Amplitude		mVpp	400		700	
Output Impedance		$\Omega$		50		
Connector						SMA female

<b>Option ISJ: Internal Sinusoidal Jitter Injection</b>						
Jitter Frequency		MHz	10		400	
Jitter Amplitude		ps	0		60	

<b>External Jitter Injection</b>						
Modulation Bandwidth		MHz	0.1		1000	
Modulation Amplitude		mVpp	0		1200	Maximum corresponds to 60 ps jitter.
Jitter Amplitude		ps	0		60	Peak-to-peak
Input Impedance		$\Omega$		50		
Connector						SMA female

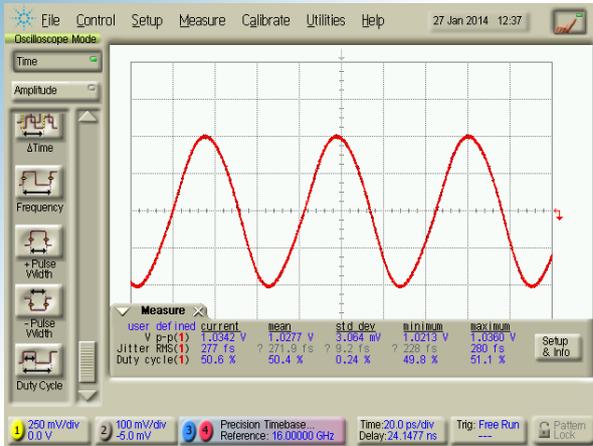

<b>Spread Spectrum Clocking</b>						
Modulation Frequency		Hz	10		100 k	
Deviation		ppm	0		20,000	Up/down/center

<b>10 MHz Ref Input</b>						
Reference Frequency	$f_{ref}$	MHz		10		
Amplitude		Vpp	0.2		3.3	
Input Impedance		$\Omega$		50		
Connector						SMA female

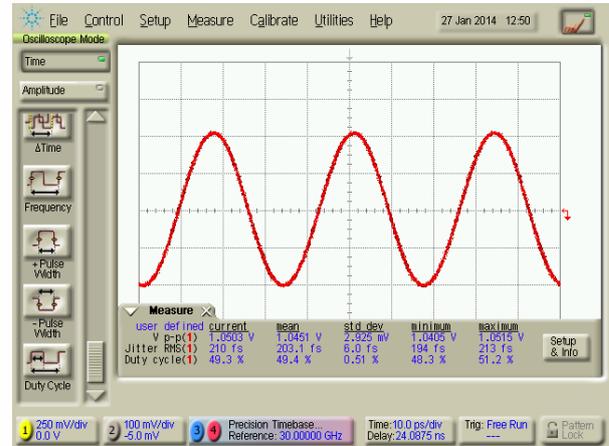

<b>General</b>						
Power Consumption		W			25	Power supplied by SHF Mainframe
Weight		kg		4		
Operating Temperature		$^{\circ}\text{C}$	10		35	Ambient temperature

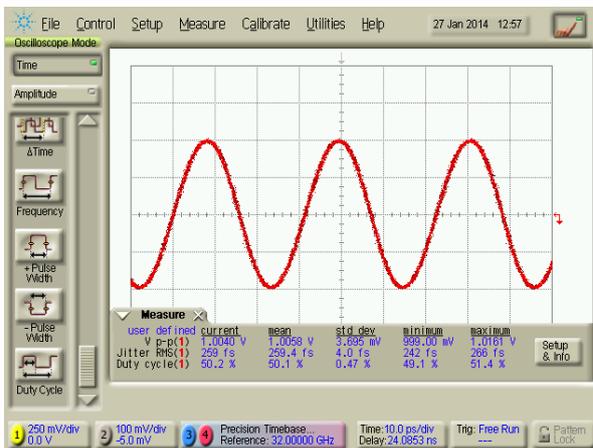

# Typical Output Waveforms

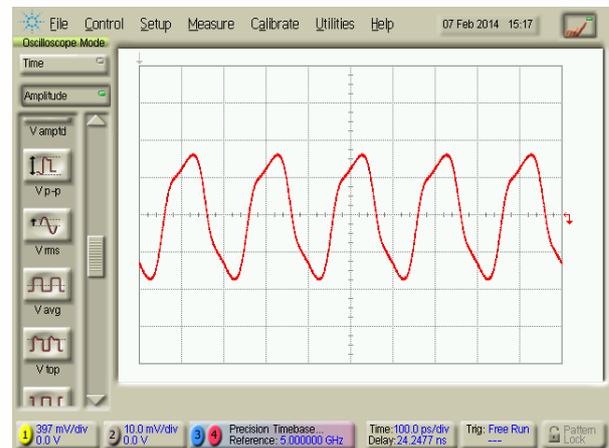

**Clock Signal at  $f_{CLK} = 16$  GHz,  $P_{out} = +4$  dBm**

**Clock Signal at  $f_{CLK} = 30$  GHz,  $P_{out} = +4$  dBm**

**Clock Signal at  $f_{CLK} = 32$  GHz,  $P_{out} = +4$  dBm**

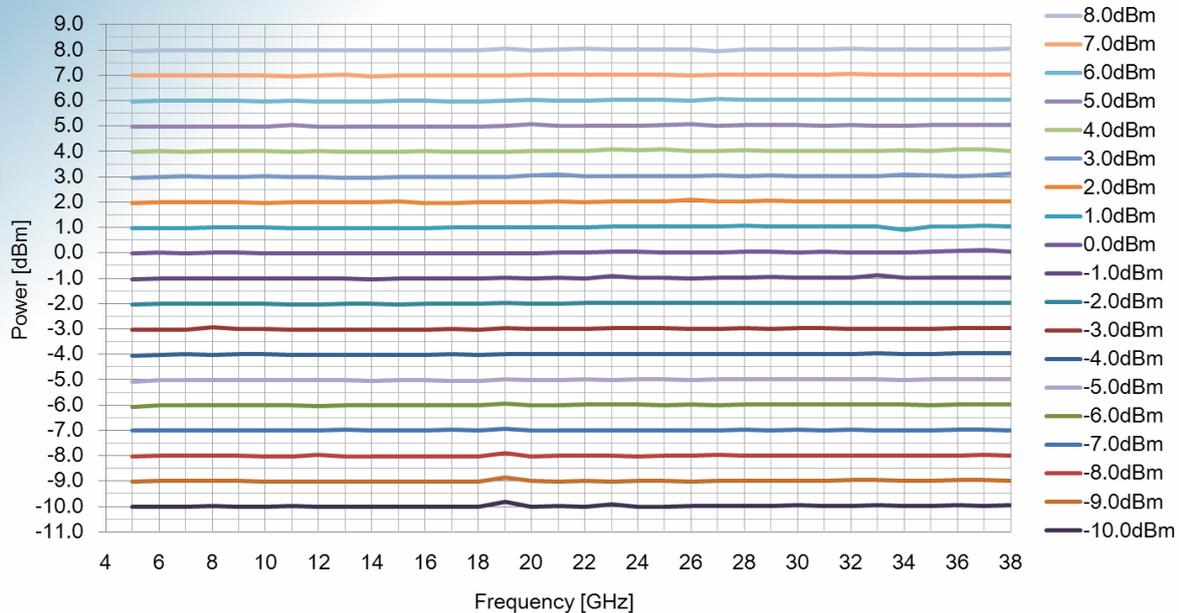

**Clock Signal at  $f_{CLK} = 5$  GHz**

Note that for clock frequencies above 10 GHz, the signal is band-pass filtered to achieve low harmonics and a nearly pure sine wave. Below 10 GHz, however, the clock signals are amplified with subsequent amplitude clipping to shorten the rise time. In the frequency range below 10 GHz, this generates noticeable higher-order harmonics. The SHF 78210 C is optimized for clock source applications in combination with SHF BERT instruments, where a short rise time is preferred.

## Output Amplitude

The following diagram shows typical amplitude measurement results using a power meter connected directly on the RF Out port for power settings from -10 to +8 dBm.

## External Jitter Injection

For additional flexibility, arbitrary jitter modulation may be applied to the high-speed clock signal. Jitter is injected by connecting a signal source such as an arbitrary waveform generator to the external modulation input. The maximum jitter amplitude is 60 ps peak-to-peak with a modulation bandwidth of up to 1 GHz. As an example, the jitter amplitude of 60 ps corresponds to a relative jitter amplitude of 2.2 unit intervals (UI) at a bit rate of 32 Gbit/s.

The jitter amplitude is calibrated using the Trigger Output signal of the SHF 78210 C which remains jitter-free even if jitter injection is used.

In combination with an SHF Bit Pattern Generator and an Error Analyzer, the SHF 78210 C enables a complete test solution for jitter tolerance tests as required by many telecommunication standards such as 100G Ethernet and 40 Gbit/s OTN, FibreChannel, InfiniBand®, PCI Express®, and Serial ATA. For further details please refer to the SHF application note „Jitter Injection using the Multi- Channel BPG“, available online at [www.shf.de](http://www.shf.de).

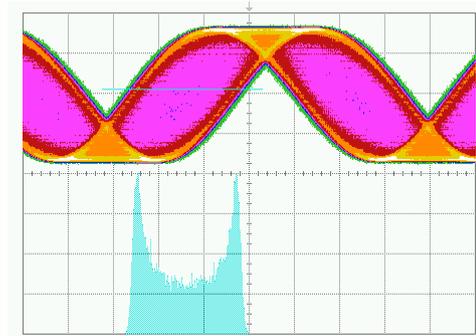

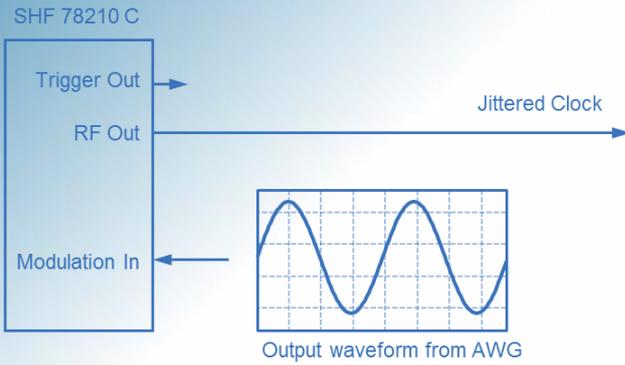

## Typical Jittered Signal Waveforms

The external modulation input can be driven by a function generator such as the Agilent 332XX family of function / arbitrary waveform generators (AWG). The waveform characteristics of the AWG determine the jitter type of the SHF 78210 C.

### Sine Wave on Modulation Input

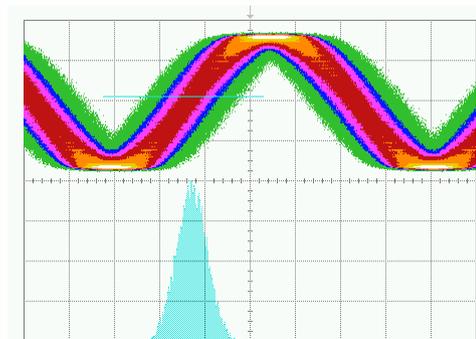

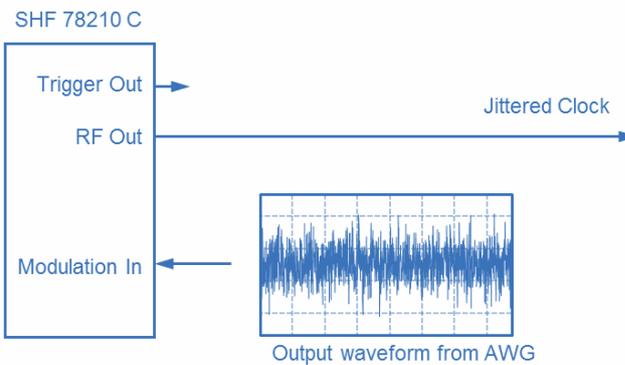

Sinusoidal jitter on 28 GHz clock.

#### AWG Setting

Waveform Sine wave  
Frequency 100 kHz  
Amplitude 70 mVpp

### Gaussian-Distributed Noise on Modulation Input

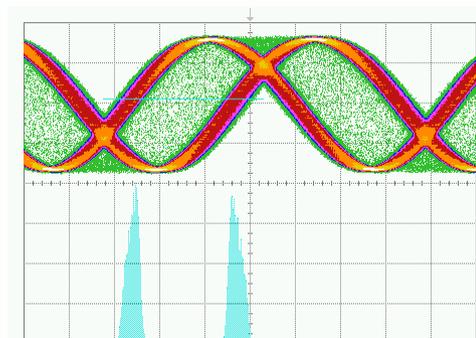

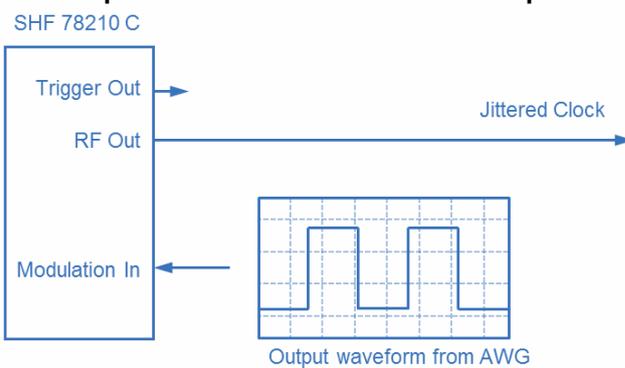

Random jitter on 28 GHz clock.

#### AWG Setting

Waveform Noise  
Amplitude 70 mVpp

### Square Waveform on Modulation Input

Peak-to-peak jitter on 28 GHz clock.

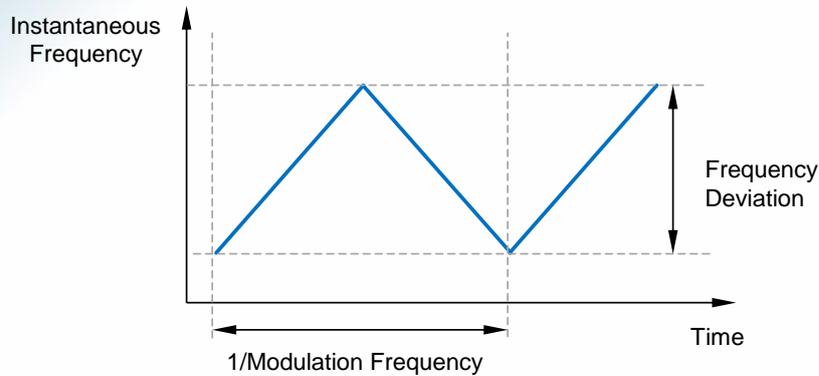

#### AWG Setting

Waveform Square  
Frequency 100 kHz  
Amplitude 70 mVpp

# Spread Spectrum Clocking

To meet the regulatory demands of electromagnetic interference several high-speed bus systems use a spread spectrum clocking (SSC) method. When SSC is enabled, the instantaneous frequency of the clock signal varies periodically with time by a small amount, i.e. the clock signal is frequency-modulated. The figure below illustrates the SSC frequency modulation with a triangular shape.

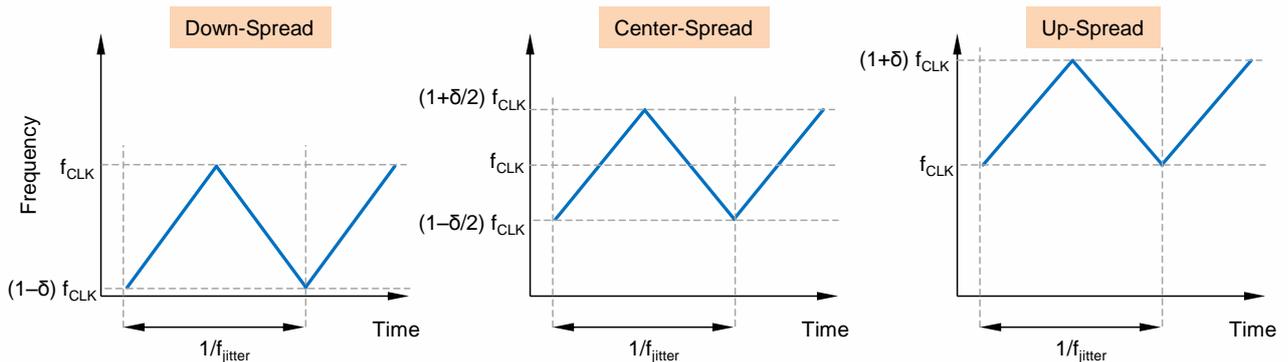

The principle of SSC is the periodic frequency modulation of a clock signal.

The key SSC parameters are the following:

- $f_{CLK}$  original clock frequency without SSC
- $\delta$  relative frequency deviation (often given in percent or ppm, parts per million)
- $f_{jitter}$  modulation frequency.

The parameters are directly accessible in the BERT Control Center software GUI or through remote programming.

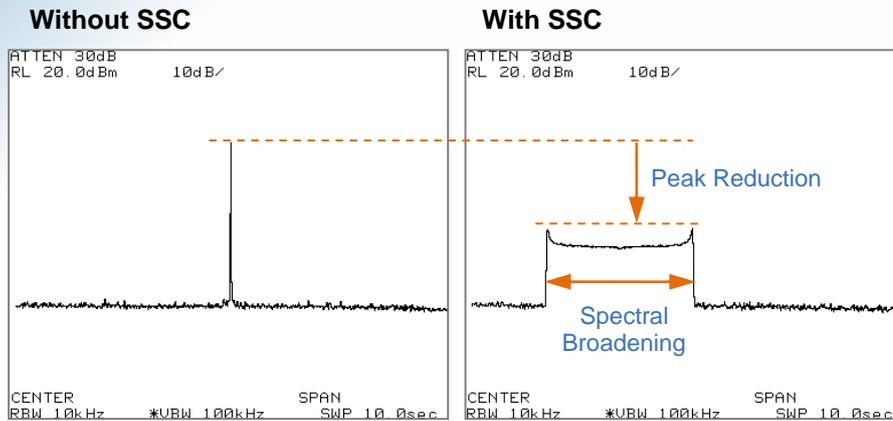

Depending on the relative position of the clock frequency and the frequency deviation, SSC can be classified into three types: down, center, and up-spread. The figure below illustrates the three configurations.

Three types of SSC.

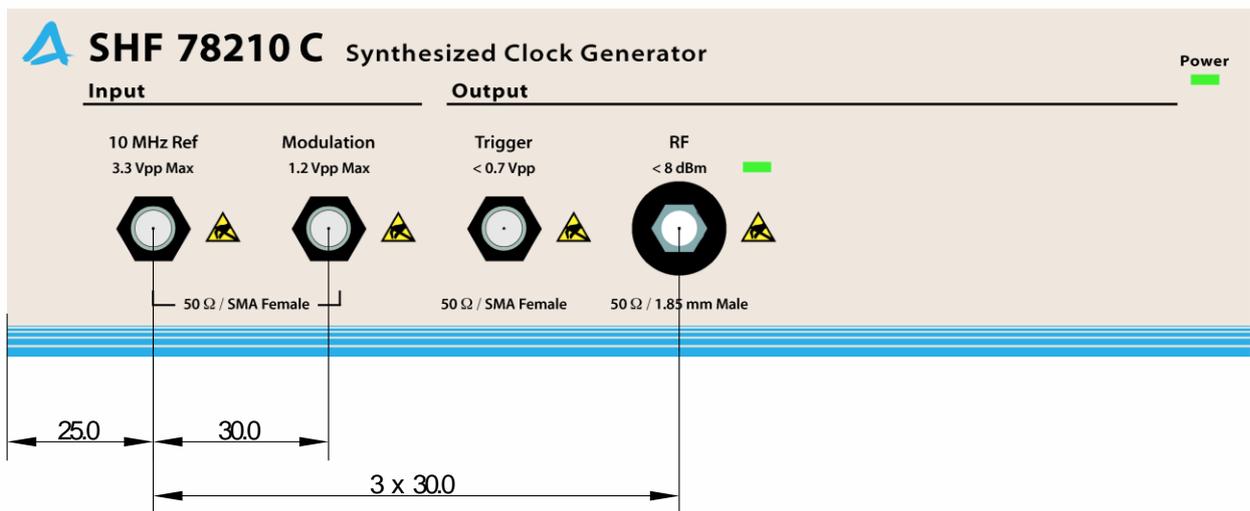

SSC, effectively, broadens the spectral peak of a clock signal so that the maximum of the power spectral density is reduced leading to less radiated emission. This is illustrated in the following spectra measured at the output of the SHF 78210 C for a 25 GHz clock with 30 kHz modulation frequency and 0.5% deviation. Note that SSC does not reduce the total signal power of the clock. Rather, it redistributes the clock's spectral components as shown in the figure below.

SHF 78210 C clock spectrum with and without SSC.

## Mechanical Drawing

All dimensions are specified in millimeters (mm).
